FINITE MULTIPLICITIES BEYOND SPHERICAL PAIRS

AVRAHAM AIZENBUD AND DMITRY GOUREVITCH

Abstract. Let \( G \) be a real reductive algebraic group, and let \( H \subset G \) be an algebraic subgroup. It is known that the action of \( G \) on the space of functions on \( G/H \) is "tame" if this space is spherical. In particular, the multiplicities of the space \( S(G/H) \) of Schwartz functions on \( G/H \) are finite in this case. In this paper we formulate and analyze a generalization of sphericity that implies finite multiplicities in \( S(G/H) \) for small enough irreducible representations of \( G \).

1. Introduction

Let \( G \) be a reductive algebraic group defined over \( \mathbb{R} \), and \( X \) be a smooth algebraic \( G \)-variety. Let \( g \) denote the Lie algebra of \( G \), \( g^* \) denote the dual space, and \( \mathcal{N}(g^*) \subset g^* \) denote the nilpotent cone. Let \( \mu : T^*X \to g^* \) denote the moment map (see §2.1 for its definition).

Definition A. (i) For a nilpotent orbit \( O \subset \mathcal{N}(g^*) \) we say that \( X \) is \( O \)-spherical if
\[
\dim \mu^{-1}(O) \leq \dim X + \frac{1}{2} \dim O.
\]

(ii) For a \( G \)-invariant subset \( \Xi \subset \mathcal{N}(g^*) \), we say that \( X \) is \( \Xi \)-spherical if it is \( O \)-spherical for every orbit \( O \subset \Xi \).

We show that \( X := G/H \) is \( O \)-spherical if and only if \( \dim O \cap h^\perp \leq \dim O/2 \), where \( h^\perp \subset g^* \) denotes the space of functionals vanishing on the Lie algebra \( h \) of \( H \). We also prove the following criterion for sphericity with respect to closures of Richardson orbits, i.e. orbits that intersect parabolic nilradicals by open dense subsets.

Theorem B (§2.2). Let \( P \subset G \) be a parabolic subgroup, let \( O_P \) denote the corresponding Richardson orbit, and \( \overline{O_P} \) denote its closure. Then \( X \) is \( \overline{O_P} \)-spherical if and only if \( P \) has finitely many orbits on \( X \).

This implies in particular that \( X \) is \{0\}-spherical if and only if \( G \) has finitely many orbits on \( X \) and that \( X \) is \( \mathcal{N}(g^*) \)-spherical if and only if \( X \) is spherical.

The proof of Theorem B is based on the following theorem, which is of independent interest.

Theorem C (§2.4). Let \( p \subset g \) be a parabolic subalgebra, and \( O \subset \overline{O_p} \) be a nilpotent orbit. Then \( \dim O \cap p^\perp = \dim O/2 \).

Key words and phrases. Representation, algebraic group, nilpotent orbit, spherical space, wave-front set, associated variety of the annihilator, non-commutative harmonic analysis, branching, invariant distribution, Schwartz space, holonomic D-module.
Let $G := G(\mathbb{R})$ denote the group of real points of $G$ and similarly $X := X(\mathbb{R})$. Let $\mathcal{M}(G)$ denote the category of finitely-generated smooth admissible Fréchet representations of moderate growth (see [Wall92 §11.5]).

Our main motivation for the notion of $O$-spherical variety is the following theorem.

**Theorem D** (See Corollary 4.2.2 below). Let $\pi \in \mathcal{M}(G)$ and let $\Xi$ denote the associated variety of the annihilator of $\pi$. If $X$ is $\Xi$-spherical then $\pi$ has finite multiplicity in $S(X)$, i.e.

$$\dim \text{Hom}_G(S(X), \pi) < \infty.$$ 

We actually prove a more general theorem, that allows to consider certain bundles on $X$, and replaces the reductivity assumption on $G$ by certain assumptions on $\pi$.

We deduce the theorem from the following theorem on invariant distributions.

**Theorem E** (See Theorem 3.2.1 below). Let $I \subset \mathcal{U}(\mathfrak{g})$ be a two-sided ideal, and let $\mathcal{V}(I) \subset \mathfrak{g}^*$ denote its associated variety. Suppose that $\mathcal{V}(I)$ lies in the nilpotent cone of $\mathfrak{g}^*$. Let $X, Y$ be $\mathcal{V}(I)$-spherical $G$-manifolds. Let $S^*(X \times Y)^{\Delta G,I}$ denote the space of tempered distributions on $X \times Y$ that are invariant under the diagonal action of $G$, and annihilated by $I$. Then

$$\dim S^*(X \times Y)^{\Delta G,I} < \infty$$

Moreover, the space $S^*(X \times Y)^{\Delta G,I}$ consists of holonomic distributions.

We prove this theorem using the theory of modules over the ring of algebraic differential operators. Namely, we use the theorem that states that the space of solutions of every holonomic D-module in tempered distributions is finite-dimensional.

Applying Theorem D to branching problems we obtain the following statements. For a nilpotent orbit $O \subset \mathfrak{g}^*$ denote by $M_G(O)$ the subcategory of $\mathcal{M}(G)$ consisting of representations with associated variety of the annihilator lying in the closure of $O$.

**Corollary F** (See Proposition 4.3.1 below). Suppose that $H$ is reductive, and let $O_1 \subset \mathfrak{g}^*$ and $O_2 \subset \mathfrak{h}^*$ be nilpotent orbits. Suppose that one of the following holds:

(a) $\dim O_1' \cap p^{-1}(O_2') \leq (\dim O_1' + \dim O_2')/2$ for any $O_1' \subset \overline{O}_1$ and $O_2' \subset \overline{O}_2$.

(b) $O_1 = O_P$ for some parabolic subgroup $P \subset G$ and $G/P$ is an $\overline{O}_2$-spherical $H$-space.

(c) $O_2 = O_Q$ for some parabolic subgroup $Q \subset H$ and $G/Q$ is an $\overline{O}_1$-spherical $G$-space.

Then for every $\pi \in M_G(O_1)$ and $\tau \in M_G(O_2)$, we have

$$\dim \text{Hom}_H(\pi|_H, \tau) < \infty$$

**Corollary G** (See §3.1.3 below). Suppose that $H$ is reductive.

(i) Let $P \subset G$ be a parabolic subgroup, and suppose that $G/P$ is a spherical $H$-variety. Then for every $\pi \in M_G(P)$, the restriction $\pi|_H$ has finite multiplicities.

(ii) Let $Q \subset H$ be a parabolic subgroup. If $Q$ is spherical as a subgroup of $G$, then for any $\tau \in M_G(Q)$, the Schwartz induction $\text{Ind}^G_H(\tau)$ has finite multiplicities.

For the case when the commutant $[g, g]$ is simple, all pairs $(H, P)$ such that $H$ is a symmetric subgroup of $G$, and $G/P$ is a spherical $H$-space are classified in [HNOO13 §5, Table 2]. More generally, a strategy for classifying all pairs $(H, P)$ of subgroups of $G$ satisfying the conditions of Corollary G is given in [APT14]. This strategy is also implemented in *loc. cit.* for $G = \text{GL}_n$.  

\footnote{See §3.1.4 below for the definition}
The pairs of subgroups $Q \subset H \subset G$ such that $H$ is a symmetric subgroup of $G$, and $Q$ is a parabolic subgroup of $H$ that is also a spherical subgroup of $G$ are classified in [HNOO13, §6, Table 3]. For some representatives of this class of pairs, $H$-multiplicities of degenerate principal series representations are studied in detail in [MOO16, FO19].

An interesting example for non-simple $[g, g]$ is the diagonal symmetric pair: $G = H \times H$, with $H$ embedded diagonally. This case gives the following corollary.

**Corollary H.** Let $H$ be a reductive group, and $P, Q \subset H$ be parabolic subgroups. Suppose that $H/P \times H/Q$ is a spherical $H$-variety, under the diagonal action.

Then for any $\pi \in \mathcal{M}_{\text{par}}(H)$ and any $\tau \in \mathcal{M}_{\text{par}}(H)$, the tensor product $\pi \otimes \tau$ has finite multiplicities as a representation of $H$.

Corollaries F and G also hold in a wider generality, that allows the groups to be non-reductive, but puts restrictions on the representations (see Definition 4.1.5). This allows to apply Corollary G to mixed models. We do so in Corollary 4.3.3 below. Let us give an example for this corollary, that can also be seen as a generalization of the Shalika model.

**Example I** (See §4.3 below). Let $G = GL_{2n}$, $R \subset G$ be the standard parabolic subgroup with Levi part $L = GL_n \times GL_n$ and unipotent radical $U = \text{Mat}_{n \times n}$, $M = \Delta GL_n \subset L$, $H := MU$. Let $O_{\text{min}} \subset m^*$ denote the minimal nilpotent orbit (which consists of rank 1 matrices), and let $\pi \in \mathcal{M}_{O_{\text{min}}}(M)$. Extend $\pi$ to a representation of $H$ by letting $U$ act trivially. Let $\psi$ be a unitary character of $H$. Then $S \text{ ind}^H_F(\pi \otimes \psi)$ has finite multiplicities.

A similar example works for the orthogonal groups $G = O_{2n}$, $L = GL_{2n}$, $M = Sp_{2n}$, and the next-to-minimal orbit $O_{\text{ntm}} \subset m^*$, which consists of matrices of rank 2 in $sp_{2n}^*$.

1.1. **Background and motivation.** Harmonic analysis on spaces with group action is a central direction of modern representation theory. So far, most of the attention was given to spherical spaces, see e.g. [Ber88, Del98, vBS05, AGRS10, AG03, SZ12, GGPW12, MW12, KO13, Kob15, KS16, SV17, KKS18, Del18, GGP20, DKKS21, Wan]. Indeed, the spherical (or real/p-adic spherical) spaces $X$ seem to be the most natural spaces to consider if one wants to analyse the entire space of functions on $X$, because of the coherence properties this space possesses, see [KO13, KS16, SV17, and AGS15 Appendix A].

However, if we restrict our attention to a subcategory of representations of the group, namely to representations with associated variety of the annihilator lying in a fixed subset of the nilpotent cone, some coherence properties hold in a wider generality, as exhibited by Theorem D. This serves as our main motivation for the notion of $\Xi$-spherical space.

1.2. **Examples.** The classification of all pairs of parabolic subgroups satisfying the condition of Corollary H is given in [Ste03]. In particular, this shows that the product of two small representations of a classical group has finite multiplicities. Also, for $GL_n$ the product of any representation $\pi \in \mathcal{M}(G)$ with any minimal representation $\tau$ has finite multiplicities. This allows to define some analogue of translation functors, by sending $\pi$ to the projection of $\pi \otimes \tau$ on the subcategory corresponding to a fixed central character.

For $H \in \{GL_n, Sp_{2n}, SO_{2n+1}\}$, all triples of parabolic subgroups such that $H$ has finitely many orbits under the diagonal action on $H/P_1 \times H/P_2 \times H/P_3$ are classified in [MWZ99].

---

2 i.e. representations such that the square of every matrix in the associated variety of the annihilator is zero.
They also show that these groups never have finitely many orbits on the quadriple product $\prod_{i=1}^4 H/P_i$ unless $P_i = H$ for some $i$.

The pairs of subgroups $Q \subset H \subset G$ satisfying the conditions of Corollary [G] with the additional restriction that $H$ is a symmetric subgroup of $G$ are classified in [HNOO13, §6, Table 3].

Given an orbit $O \subset \mu(X) \subset g^*$ it is natural to ask whether a strict inequality $\dim \mu^{-1}(O) < \dim X + \dim O/2$ is possible. In Proposition 2.2.2 below we show that it is not possible if $O$ is a Richardson orbit. However, in Appendix B below, Ido Karshon shows that for non-Richardson $O$ it is possible. In this example $X = G/H$, and in fact it is computed that $\dim O \cap h^\perp < \dim O/2$. This is interesting since the scheme-theoretic intersection of $O$ with $h^\perp$ is co-isotropic with respect to the Kirillov-Kostant-Souriau symplectic form on $O$, but obviously in this case the intersection is not reduced. We wonder if such an example is possible for a spherical subgroup $H \subset G$. Under additional conditions that $H$ is either solvable or symmetric, this is not possible by

Let us now give an example of an $O$-spherical subgroup for a non-Richardson orbit $O$, computed in [GS21, §9 and Appendix A], motivated by the local $\theta$-correspondence in type II.

**Example 1.2.1.** Let $G := GL_n \times GL_k \times Sp_{2nk}$ (when we pass to real groups we will have to consider a double cover). Let $i$ be the composition of the two natural embeddings

$$GL_n \times GL_k \hookrightarrow GL_{nk} \hookrightarrow Sp_{2nk},$$

and let $H$ be the graph of $i$. Let $O := O_{\text{reg}} \times O_{\text{reg}} \times O_{\text{min}}$. Then $H$ is $O$-spherical.

The theory of local $\theta$-correspondence implies a strong form of multiplicity one in this case, if we replace $G$ by its metaplectic cover. This serves as an evidence that Theorem D may generalize to covering groups.

1.3. Related results. It is proven in [KO13] that for spherical subgroups $H \subset G$, the $H$-multiplicities of all irreducible admissible representations are universally bounded. The literal analogue of this result to $O$-spherical subgroups representations cannot hold already for $O = \{0\}$: every subgroup $H \subset G$ is $\{0\}$-spherical, including the trivial $H$, $\mathcal{M}_{\{0\}}(G)$ consists of finite-dimensional representations, and multiplicities equal the dimension. A possible general conjecture is that it is bounded by $c_O^{\text{geom}}$ — some total multiplicity (taken with some coefficients of geometric nature) of $K$-orbits lying in $O$ in the associated variety of $\pi$ (which is a finer invariant than the annihilator variety).

By Theorems [B] and [D] a sufficient condition for every $\pi \in \mathcal{M}_{O^P}(G)$ to have finite $H$-multiplicities is that $H$ has finitely many orbits on $G/P$. The following result provides a necessary condition in similar terms.

**Theorem 1.3.1 ([Tan19, Theorem 2.4]).** Let $P \subset G$ be a parabolic subgroup. If all degenerate principal series representations of the form $\text{Ind}_P^G \sigma$, with $\dim \sigma < \infty$ have finite $H$-multiplicities, then $H$ has finitely many orientable orbits on $G/P$.

**Corollary J.** Let $P \subset G$ be a parabolic subgroup defined over $\mathbb{R}$, and let $P$ be the corresponding parabolic subgroup of $G$. Suppose that for all but finitely many orbits of $H$ on $G/P$, the set of real points is non-empty and orientable. Then the following are equivalent.

(i) $H$ is $O_P$-spherical, where $O_P$ denotes the Richardson orbit of $P$. 

(ii) Every $\pi \in \mathcal{M}_{OP}(G)$ has finite multiplicities. 

(iii) $H$ has finitely many orbits on $G/P$. 

(iv) $H$ has finitely many orbits on $G/P$. 

The assumption of the corollary holds in particular if $H$ and $G$ are complex reductive groups.

When the conditions of the corollary are not satisfied, the finiteness of $H \backslash G/P$ is not necessary. Indeed, when $P$ is a minimal parabolic subgroup defined over $\mathbb{R}$, the finiteness of $H \backslash G/P$ implies that all $\pi \in \mathcal{M}(G)$ have finite multiplicities, by [KO13]. However, for general parabolic subgroups, the finiteness of $H \backslash G/P$ is not sufficient, and a series of counterexamples is provided in [Tau18]. These are examples of non-spherical $H \subset G$, and a parabolic $P \subset G$ for which $H \backslash G/P$ is finite, but the $H$-multiplicities of degenerate principal series representations $\text{Ind}^G_P \chi$ are infinite. For a very explicit description of the basic example in these series see [Tau19, Outline of the proof of Theorem 2.2].

The recent work [GS21] allows also to give a microlocal necessary condition for the non-vanishing of the multiplicity space. For this purpose we remark that by [BB85, Jos85] (cf. [Vog91, Corollary 4.7]), for any irreducible $\pi \in \mathcal{M}(G)$, the annihilator variety $\text{An}V(\pi)$ is the closure of a single orbit, that we will denote $O(\pi)$.

**Theorem 1.3.2 (GS21, §9).** Let $\pi \in \mathcal{M}(G)$ be irreducible. Suppose that $\pi$ is a quotient of $S(X)$, for some $O(\pi)$-spherical $G$-manifold $X$. Then $O(\pi) \subset \text{Im} \mu(X)$. Moreover, if $X = G/H$ then

$$2 \dim O(\pi) \cap \mathfrak{h}^\perp = \dim O(\pi).$$

In [AGKL16], it is shown that for any $\mathbb{R}$-spherical subgroup $H \subset G$, and most choices of a maximal compact subgroup $K \subset G$, the Harish-Chandra module of any $\pi \in \mathcal{M}(G)$ is finitely-generated over $\mathfrak{h}$. This implies both finite multiplicities, and finiteness of higher homology groups. We wonder whether the same holds for $\Xi$-spherical subgroups and $\pi \in \mathcal{M}_\Xi(G)$.

Theorem 1 implies that the relative characters of $\pi \in \mathcal{M}_\Xi(G)$ corresponding to $\Xi$-spherical subgroups are holonomic. For spherical subgroups, it is further shown in [Li20] that the relative characters are regular holonomic. We conjecture that this holds for $\Xi$-spherical subgroups as well, and hope to prove that at least for the case when $\Xi$ is a closure of a Richardson orbit, using Theorem B and generalizing the proof in [Li20].

1.4. Open questions. The first open question is to give a necessary and sufficient conditions for finite $H$-multiplicities in $\mathcal{M}_\Xi(G)$. As discussed above, in some cases our sufficient condition is also necessary, but in others it is not.

Another goal, which is probably easier, is to extend our results to covering groups.

Further, we can consider an ”additive character” $\chi$ of $\mathfrak{h}$, i.e. a differential of a group map $H \to G_a$. Then, we think that under some conditions on $\mathfrak{h}$ and $\chi$, in all the statements above we can replace the multiplicity spaces by $\text{Hom}_h(\pi, \chi)$, and the set $\mathfrak{h}^\perp$ by $p_h^{-1}(\chi)$, where $p_h : \mathfrak{g}^* \to \mathfrak{h}^*$ is the standard projection. This would imply the finiteness of certain generalized Whittaker models. Such a twisted version of Theorem 1.3.2 is proven in [GS21, §9].

We would also like to find an example in which $O \cap \mathfrak{h}^\perp$ has dimension $\dim O/2$, but for some $O' \subset O$ we have $\dim O' \cap \mathfrak{h}^\perp > \dim O'/2$, or prove that such examples do not exist.

Finally, we are very much interested in the non-archimedean analogues of our results.
1.5. **Structure of the paper.** In §2 we prove Theorems \[ \text{B} \] and \[ \text{C} \] as well as some other geometric results needed for the corollaries on branching problems.

In §3 we prove Theorem \[ \text{E} \] by showing that the system of differential equations satisfied by the distributions in question is holonomic.

In §4 we deduce Theorem \[ \text{D} \] from Theorem \[ \text{E} \] and then deduce Corollaries \[ \text{F} \] and \[ \text{F} \] from Theorem \[ \text{D} \] and the geometric results in §2. In Appendix A we prove a geometric proposition \[ \text{2.1.2} \] on non-reductive groups. Finally, in Appendix B we give an example in which the inequality in Definition \[ \text{A} \] is strict.

1.6. **Acknowledgements.** We thank Joseph Bernstein, Shachar Carmeli, and Eitan Sayag for fruitful discussions.

## 2. Geometry

### 2.1. Preliminaries and notation.

From now and till the end of the section we let \( \mathbb{G} \) be a connected complex linear algebraic group. We will be mainly interested in the case of reductive \( \mathbb{G} \). Let \( \mathfrak{g} \) denote the Lie algebra of \( \mathbb{G} \), and \( \mathfrak{g}^* \) denote the dual space.

In general, we will denote algebraic groups by boldface letters, and their Lie algebras by the corresponding Gothic letters.

We start with the definition of the moment map. Let \( X \) be an algebraic \( \mathbb{G} \)-manifold. For any point \( x \in X \), let \( a_x : \mathbb{G} \to X \) denote the action map, and \( da_x : \mathfrak{g} \to T_xX \) denote its differential.

The moment map \( \mu := \mu_X : T^*X \to \mathfrak{g}^* \) is defined by

\[
\mu_X(x, \xi)(\alpha) := \xi(da_x(\alpha))
\]

**Lemma 2.1.1.** Let \( S := \mu_X^{-1}(\{0\}) \). Then the following are equivalent:

1. \( \mathbb{G} \) has finitely many orbits on \( X \).
2. \( S \) is equidimensional of dimension \( \dim X \).
3. \( \dim S \leq \dim X \)

**Proof.** (i) \( \Rightarrow \) (ii): The set \( S \) is the union of conormal bundles to orbits. The conormal bundle to each orbit is irreducible of dimension \( \dim X \). (ii) \( \Rightarrow \) (iii) is obvious. (iii) \( \Rightarrow \) (i): Denote by \( p_X : T^*X \to X \) the natural projection. For every \( \mathbb{G} \)-orbit \( R \subset X \) we have \( S \cap p_X^{-1}(R) = CN_R \).

By Rosenlicht’s theorem, there is an open non-empty subset \( U \subset X \) that has a geometric quotient by \( \mathbb{G} \). Applying this theorem again to the complement \( X \setminus U \), and further by induction, we obtain a stratification of \( X \) by such sets \( T_i \). If for some \( i \), \( T_i \) is not a finite union of orbits, then \( \dim S \cap p_X^{-1}(R) > \dim X \), contradicting the assumption. \( \square \)

Denote by \( U_\mathbb{G} \subset \mathbb{G} \) the unipotent radical of \( \mathbb{G} \), and by \( u_\mathfrak{g}^+ \subset \mathfrak{g}^* \) the space of functionals on \( \mathfrak{g} \) that vanish on \( u_\mathfrak{g} \). We will call an element \( \varphi \in \mathfrak{g}^* \) nilpotent if \( \varphi \in u_\mathfrak{g}^+ \), and the closure of the coadjoint orbit \( \mathbb{G} \cdot \varphi \) includes 0. Let \( \mathcal{N}(\mathfrak{g}^*) \subset \mathfrak{g}^* \) denote the nilpotent cone. By Kostant’s theorem, \( \mathcal{N}(\mathfrak{g}^*) \) consists of finitely many coadjoint \( \mathbb{G} \)-orbits. Indeed, these orbits are in bijection with the nilpotent coadjoint orbits of the reductive quotient \( \mathbb{R}_\mathbb{G} := \mathbb{G} / U \) under the identification \( \mathcal{R}_\mathfrak{g} \cong u_\mathfrak{g}^+ \subset \mathfrak{g}^* \).

The requirement \( \varphi \in u_\mathfrak{g}^+ \) is motivated by the following proposition.

**Proposition 2.1.2.** (See Appendix A below). Let \( \Xi \subset \mathfrak{g}^* \) be a closed conical subset that is a union of finitely many orbits. Then \( \Xi \subset u_\mathfrak{g}^+ \).
We will say that a subgroup $P \subset G$ is parabolic if it is the preimage of a parabolic subgroup of $R_G$ under the projection $G \to R_G$.

**Definition 2.1.3.** Let $P \subset G$ be a parabolic subgroup, and let $p^\perp \subset g^*$ denote the space of functionals vanishing on $p$. It is easy to see that $p^\perp \subset N(g^*)$, and thus there exists a unique nilpotent orbit that intersects $p^\perp$ by an open dense subset. It is called the Richardson orbit, and we will denote it by $O_P$, and its closure by $\overline{O_P}$.

It is easy to see that $\overline{O_P} = G : p^\perp$. For more information on Richardson orbits we refer the reader to [CM92, §7.1].

The definition of $O$-sphericity and $\Xi$-sphericity for non-reductive groups is identical to the one given in Definition [A]. Theorems [B] and [C] are also valid for non-reductive groups, and their proofs below work in this generality.

**2.2. $\Xi$-sphericity criteria.**

**Proof of Theorem [B].** Recall that $\mu : T^*X \to g^*$ denotes the moment map. Let $S := \mu^{-1}(p^\perp)$. Note that $S$ also equals the preimage of zero under the moment map for the action of $P$ on $X$. Thus, Lemma [2.1.1] implies that $P$ has finitely many orbits on $X$ if and only if $\dim S \leq \dim X$. Further, $\dim S = \max_{O \subset \overline{O_P}} \dim \mu^{-1}(p^\perp \cap O)$. Since the map $\mu$ is $G$-invariant, for any orbit $O$, the fibers of all its points are isomorphic. Thus

$$\dim \mu^{-1}(p^\perp \cap O) = \dim \mu^{-1}(O) + \dim p^\perp \cap O - \dim O$$

By Theorem [C] for every $O \subset \overline{O_P}$ we have $\dim p^\perp \cap O - \dim O = -\dim O/2$, and thus $\dim \mu^{-1}(p^\perp \cap O) = \dim \mu^{-1}(O) - \dim O/2$, and thus $\dim S \leq \dim X$ if and only if for every $O \subset \overline{O_P}$ we have $\dim \mu^{-1}(O) \leq \dim X + \dim O/2$ which exactly means that $X$ is $\overline{O_P}$-spherical. \qed

Applying this theorem to the case when $G$ is reductive and $P$ is a Borel subgroup, we obtain the following corollary.

**Corollary 2.2.1.** If $G$ is reductive then the following are equivalent

(a) $X$ is $O$-spherical for every $O$
(b) $X$ is spherical.

A similar argument gives the following statement for Richardson orbits.

**Proposition 2.2.2.** Let $O \subset g^*$ be a Richardson nilpotent orbit that lies in the image of $\mu$. Then

$$\dim \mu^{-1}(O) \geq \dim X + \dim O/2.$$  

**Proof.** Let $P \subset G$ be a parabolic subgroup such that $O = O_P$. As in the previous theorem, let $S := \mu^{-1}(p^\perp) \subset T^*X$. Then $S$ is a union of conormal bundles to $P$-orbits on $X/P$ and thus the dimension of every irreducible component of $S$ is at least $\dim X$. Let $Y$ be an irreducible component of $S$ that intersects $\mu^{-1}(O)$. Then $\dim Y = \dim (O \cap p^\perp) + \dim \mu^{-1}(\varphi)$, for some $\varphi \in O \cap p^\perp$. But since the fibers under $\mu$ of all points in $O$ are isomorphic, we have $\dim \mu^{-1}(\varphi) = \dim \mu^{-1}(O) - \dim O$. By Theorem [C], $\dim O \cap p^\perp = \dim O/2$. Altogether, we get

$$\dim \mu^{-1}(O) = \dim \mu^{-1}(\varphi) + \dim O = \dim Y - \dim (O \cap p^\perp) + \dim O \geq \dim X + \dim O/2.$$  

\qed
The assumption that $O$ is Richardson cannot be omitted: in Appendix [B] below we give an example of a homogeneous space $X$ and a non-Richardson orbit $O$ such that $\dim \mu^{-1}(O) < \dim X + \dim O/2$.

Let us now make the notion of $O$-spherical explicit for homogeneous varieties. Let $H \subset G$ be an algebraic subgroup, and let $\mathfrak{h}$ be its Lie algebra. Let $\mathfrak{h}^\perp \subset \mathfrak{g}^*$ denote the space of functionals vanishing on $\mathfrak{h}$. For any $gH \in G/H$, identify the cotangent space to $G/H$ at $gH$ with $g \cdot \mathfrak{h}^\perp \subset \mathfrak{g}^*$. Under this identification the moment map sends $(gH, \lambda) \in T^*(G/H)$ to $\lambda \in \mathfrak{g}^*$. Thus, the image of $\mu$ is $G \cdot \mathfrak{h}^\perp$.

**Lemma 2.2.3.** $\dim \mu^{-1}(O) = \dim(G/H) + \dim O \cap \mathfrak{h}^\perp$.

**Proof.** $\mu^{-1}(O) = \{(gH, \xi) | \xi \in O \cap g \cdot \mathfrak{h}^\perp\}$. Projecting it on $G/H$ we obtain the required equality. \hfill $\Box$

**Corollary 2.2.4.** $G/H$ is $O$-spherical if and only if $\dim O \cap \mathfrak{h}^\perp \leq \dim O/2$.

We will say that $H$ is $O$-spherical if $G/H$ is $O$-spherical, and similarly for any $G$-invariant subset $\Xi \subset \mathcal{N}(\mathfrak{g}^*)$.

**Lemma 2.2.5.** The subgroup $H \subset G$ is $O$-spherical if and only if the subgroup $HU_G \subset G$ is $O$-spherical.

**Proof.** By Lemma 2.2.3 and using the fact that $O \subset \mathfrak{u}_G^\perp$ we have

$H \subset G$ is $O$-spherical $\iff \dim O \cap \mathfrak{h}^\perp \leq \dim O/2$$\iff \dim O \cap (\mathfrak{h} + \mathfrak{u})^\perp \leq \dim O/2 \iff HU_G \subset G$ is $O$-spherical. \hfill $\Box$

**Lemma 2.2.6.** Let $\Xi \subset \mathfrak{t}_G^*$ be a closed conical subset, and let $X$ be a $\Xi$-spherical algebraic $R_G$-manifold. Embed $R_G$ into $G$ and consider the induced $G$-manifold $G \times_{R_G} X$. Then $G \times_{R_G} X$ is also $\Xi$-spherical.

**Proof.** For any $\varphi \in \mathfrak{u}_G^\perp \subset \mathfrak{g}^*$, the fiber of $\varphi$ under the moment map $\mu_{G \times_{R_G} X}$ is isomorphic to $G \times_{R_G} \mu_{X}^{-1}(\varphi)$. Thus

$$\dim \mu_{G \times_{R_G} X}^{-1}(\Xi) = \dim U_G + \dim \mu_{R_G}^{-1}(\Xi) \leq \dim U_G + \dim X = \dim G \times_{R_G} X$$

2.3. **Branching problems.** Let $H \subset G$ be an algebraic subgroup, and consider the subgroup $\Delta H \subset G \times H$. Let $O_1 \subset \mathfrak{g}^*$ and $O_2 \subset \mathfrak{h}^*$ be nilpotent orbits. In this subsection we give equivalent conditions to the statement

$$(1) \quad G \times H/\Delta H \text{ is } \overline{O_1} \times \overline{O_2} \text{-spherical } G \times H \text{-space}$$

**Proposition 2.3.1.** (i) $[1]$ holds if and only if for every two orbits $O'_1 \subset \overline{O_1}$ and $O'_2 \subset \overline{O_2}$, we have

$$\dim \{(\varphi, \psi) \in O'_1 \times O'_2 | \varphi|_H = \psi\} \leq (\dim O_1 + \dim O_2)/2$$

(ii) If $O_1 = O_P$ for some parabolic subgroup $P \subset G$, then $[1]$ holds if and only if $G/P$ is an $\overline{O_2}$-spherical $H$-space.
Theorem C, it is easy to see that \( \text{dim} \ G \) is an \( \mathcal{O}_1 \)-spherical \( G \)-space.

**Proof.** Fix nilpotent orbits \( O'_1 \subset \mathcal{O}_1 \) and \( O'_2 \subset \mathcal{O}_2 \), and denote
\[
\Upsilon := \{ (\varphi, \psi) \in O'_1 \times O'_2 | \varphi|_h = \psi \} \quad \text{and} \quad d := \text{dim} \ \Upsilon
\]
To prove (i), identify \( G \times H/\Delta H \) with \( G \), with \( G \) acting on the left and \( H \) acting on the right, and let \( \mu : T^* G \rightarrow g^* \times h^* \) denote the moment map. Then
\[
\text{dim} \ \mu^{-1}(O'_1 \times O'_2) = d + \text{dim} \ G
\]
and thus
\[
\text{dim} \ \mu^{-1}(O'_1 \times O'_2) \leq \text{dim} \ G + (\text{dim} \ O'_1 + \text{dim} \ O'_2)/2 \iff d \leq (\text{dim} \ O'_1 + \text{dim} \ O'_2)/2
\]
To prove (ii), denote
\[
S_P := \{ (g, \varphi, \psi) \in G \times O'_1 \times O'_2 | \varphi|_h = \psi, \quad \text{and} \quad g \cdot \varphi \in p^\perp \}.
\]
To compare the dimension of \( S_P \) to \( d \), we first note that for every \( \varphi \in O'_1 \), the dimension of the set \( \{ g \in G | g \cdot \varphi \in p^\perp \} \) equals \( \text{dim} \ G - \text{dim} \ O'_1 \cap p^\perp \). This in turn equals
\[
\text{dim} \ G - \text{dim} \ O'_1 + \frac{1}{2} \text{dim} \ O'_1 = \text{dim} \ G - \text{dim} \ O'_1/2
\]
since \( \text{dim} \ O'_1 \cap p^\perp = \text{dim} \ O'_1/2 \) by Theorem C. Thus, every fiber of the natural projection \( S_P \rightarrow \Upsilon \) has dimension \( \text{dim} \ G - \text{dim} \ O'_1/2 \), and thus \( \text{dim} \ S_P = d + \text{dim} \ G - \text{dim} \ O'_1/2 \).

Now let \( \nu_1 : T^*(G/P) \rightarrow h^* \) denote the moment map. Then
\[
\text{dim} \ \nu_1^{-1}(O'_2) = \text{dim} \ S_P - \text{dim} \ P = d + \text{dim}(G/P) - \text{dim} \ O'_1/2.
\]
Thus
\[
d \leq (\text{dim} \ O'_1 + \text{dim} \ O'_2)/2 \quad \forall O'_1 \iff \text{dim} \ \nu_1^{-1}(O'_2) \leq \text{dim}(G/P) + \text{dim} \ O'_2/2
\]
Since by definition, \( G/P \) is an \( \mathcal{O}_2 \)-spherical \( H \)-space if and only if
\[
\text{dim} \ \nu_1^{-1}(O'_2) \leq \text{dim}(G/P) + \text{dim} \ O'_2/2 \quad \forall O'_2 \subset \mathcal{O}_2
\]
(iii) holds.

To prove (iii), denote
\[
S_Q := \{ (g, \varphi, \psi) \in G \times O'_1 \times O'_2 | g \varphi|_h = \psi, \quad \text{and} \quad \psi \in q^\perp \}.
\]
This set is naturally isomorphic to \( G \times (\Upsilon \cap (\mathcal{O}_1 \times q^\perp)) \). Since \( \text{dim} \ O'_2 \cap q^\perp = \text{dim} \ O'_2/2 \) by Theorem C, it is easy to see that \( \text{dim} \ S_Q = d + \text{dim} \ G - \text{dim} \ O'_2 \).

Now let \( \nu_2 : T^*(G/Q) \rightarrow g^* \) denote the moment map. Then
\[
\text{dim} \ \nu_2^{-1}(O'_1) = \text{dim} \ S_Q - \text{dim} \ Q = d + \text{dim}(G/Q) - \text{dim} \ O'_2/2.
\]
Thus
\[
d \leq (\text{dim} \ O'_1 + \text{dim} \ O'_2)/2 \forall O'_2 \iff \text{dim} \ \nu_2^{-1}(O'_1) \leq \text{dim}(G/Q) + \text{dim} \ O'_1/2
\]
Since by definition, \( G/Q \) is an \( \mathcal{O}_1 \)-spherical \( G \)-space if and only if \( \text{dim} \ \nu_2^{-1}(O'_1) \leq \text{dim}(G/Q) + \text{dim} \ O'_1/2 \) for every \( O'_1 \subset \mathcal{O}_1 \), (iii) holds. \( \square \)
2.4. Proof of Theorem [C]. Without loss of generality we can assume that $G$ is reductive. Let us first prove an inequality in one direction.

**Lemma 2.4.1.** \( \dim O \cap p^1 \leq \dim O/2 \)

**Proof.** Let $\nu : T^*(G/P) \to g^*$ denote the moment map, and let $S$ be the preimage of $O \cap p^1$. Since $P$ has finitely many orbits on $G/P$, \( \dim G/P \geq \dim S \). For any $\varphi \in O \subset \overline{O}_P$, the fiber has dimension

\[
\dim \nu^{-1}(\varphi) = \dim \{ g \in G | g\varphi \in p^1 \} - \dim P = \dim (O \cap p^1) + \dim G_{\varphi} - \dim P = \dim (O \cap p^1) + \dim G - \dim O - \dim P = \dim (G/P) - \dim O + \dim (O \cap p^1)
\]

Thus, \( \dim S = \nu^{-1}(O \cap p^1) \), and \( \dim G/P \geq \dim S \), we obtain

\[
\dim G/P \geq \dim S = \dim G/P - \dim O + 2 \dim (O \cap p^1), \quad \text{and thus } O \cap p^1 \leq \dim O/2 \]

□

For the proof of the other direction we will need the following notation and the following lemma, which is probably known.

For any semi-simple element $h \in g$, any $ad(h)$-invariant subspace $u \subset g$, and any integer $i \in \mathbb{Z}$, denote

\[
u^h : = \{ \alpha \in u | [h, \alpha] = i \} \quad \text{and} \quad u^h_{\geq i} := \bigoplus_{j \geq i} u^h_j
\]

**Lemma 2.4.2.** Let $(e, h, f)$ be an $\mathfrak{sl}_2$-triple in $g$, and let $v := g_{\geq 2}$. Let $e' \in v \cap G \cdot e$. Then $ad(e')$ has no kernel on $g_{<0}$.

**Proof.** Let $k$ be the dimension of the kernel of $ad(e')$ on $g_{<0}$. Then

\[
\dim G \cdot e = \dim G \cdot e' = \dim ad(e')(g) \leq \dim ad(e')(g_{<0}) + \dim ad(e')(g_{\geq 0}) \leq \dim g_{<0} - k + \dim g_{\geq 2} = \dim g - \dim g^e - k = \dim G \cdot e - k
\]

Thus, $k = 0$. □

**Proof of Theorem [C].** Consider the Springer resolution $E \to \overline{O}$. To define it, choose an $\mathfrak{sl}_2$-triple $(e, h, f)$ in $g$ with $e \in O$. Let $q := g_{\geq 0}$, and $Q \subset G$ be the corresponding parabolic subgroup. Let $v = g_{\geq 2}$. Then $E$ is defined to be the subbundle

\[
E = \{ (qQ, \alpha) \in T^*(G/Q) | \alpha \in v \}
\]

The resolution map $\nu : E \to \overline{O}$ is the restriction of the moment map. Let $S := \nu^{-1}(O \cap p^1)$. Then $\dim S = \dim O \cap p^1$.

Fix a Cartan subalgebra $t \subset g$ that includes $h$. We have $t \subset q$. Replacing $P$ by its conjugate we will also assume that $t \subset p$. Pick a set of representatives $W$ for the Weyl group corresponding to $t$. By the Bruhat decomposition, each double coset $PqQ$ intersects $W$. 

Denote $R := \{ w \in W \mid p^+ \cap Ad(w)u \cap O \neq \emptyset \}$. For any $g \in G$, denote by $\overline{g} \in G/Q$ the corresponding coset. Since $P \backslash G/Q$ is finite, we have

$$
\text{dim } S = \max_{w \in R} \dim (CN^{G/Q}_{Pw} \cap E) = \dim G/Q - \min_{w \in R} \text{codim}(E_{Pw}, CN^{G/Q}_{Pw, Pw}) = \dim G/Q - \min_{w \in R} \dim (Ad(w)(p^+))^h_1
$$

Since

$$
\dim O/2 = (\dim g - \dim g^e)/2 = \dim v + \dim g^h_1/2 = \dim G/Q - \dim g^h_1/2,
$$

it is enough to show that for every $w \in R$, we have $\dim (Ad(w)(p^+))^h_1 \geq \dim g^h_1/2$. Let $w \in R$. By the definition of $R$, there exists $e' \in v \cap Ad(w)(p^+) \cap O$. Then by Lemma 2.4.2, $\text{ad}(e')$ has no kernel on $g^h_1$. Thus, $e'$ defines a symplectic form $\omega$ on $g^h_1$ by $\omega(\alpha, \beta) := (e', [\alpha, \beta])$, where $(\cdot, \cdot)$ denotes the Killing form. Let $Z \in t$ be such that $Ad(w)(p^+) = g^Z_0$. Then it is enough to show that $\dim (g^Z_{\leq 0})_{1}^h \leq \dim g^h_1/2$. Choose a Cartan involution $\theta$ that on $t$ equals $-Id$. We have

$$
\dim (g^Z_{\leq 0})_{1}^h = \dim \theta((g^Z_{\leq 0})_1^h) = \dim (g^Z_{\leq 0})_{-1}^h
$$

Finally, we show that $(g^Z_{\geq 0})_{-1}^h$ is isotropic with respect to $\omega$. Indeed, for any $\alpha, \beta \in (g^Z_{\geq 0})_{-1}^h$, we have $[\alpha, \beta] \in g^Z_0$, and since $e' \in g^Z_0$ we have $\omega(\alpha, \beta) = (e', [\alpha, \beta]) = 0$. \hfill \Box

### 3. Invariant distributions and D-modules

In sections 3 and 4 all the algebraic varieties and algebraic groups we will consider will be defined over $\mathbb{R}$. We will use boldface letters like $X, G$ to denote these algebraic varieties and groups, and the corresponding letters in regular font (like $X, G$) to denote their real points. The Gothic letters (like $g$) will denote the complexified Lie algebras.

#### 3.1. Preliminaries and notation.

##### 3.1.1. D-modules.

We will use the theory of D-modules on complex algebraic manifolds. We will now recall some facts and notions that we will use. For a good introduction to the algebraic theory of D-modules, we refer the reader to [Ber] and [Bor87]. For a short overview, see [AG09, Appendix B]. By a **D-module** on a smooth algebraic variety $X$, we mean a quasi-coherent sheaf of right modules over the sheaf $D_X$ of algebras of algebraic differential operators. By a **finitely generated D-module** on a smooth algebraic variety $X$ we mean a coherent sheaf of right modules over the sheaf $D_X$. Denote the category of $D_X$-modules by $\mathcal{M}(D_X)$.

For a smooth affine variety $V$, we denote $D(V) := D_V(V)$. Note that the category $\mathcal{M}(D_V)$ of D-modules on $V$ is equivalent to the category of $D(V)$-modules. We will thus identify these categories.

The algebra $D(V)$ is equipped with a filtration which is called the geometric filtration and defined by the degree of differential operators. The associated graded algebra with respect to this filtration is the algebra $O(T^*V)$ of regular functions on the total space of the cotangent bundle of $V$. This allows us to define the **singular support** of a finitely generated D-module $M$ on $V$ in the following way. Choose a good filtration on $M$, i.e., a filtration such that the associated graded module is a finitely-generated module over $O(T^*V)$, and define the singular support $SS(M)$ to be the support of this module. One can show that the singular support does not
depend on the choice of a good filtration on \( M \). By Bernstein’s inequality, \( \dim SS(M) \geq \dim V \).

If for every \( x \in V \) we have \( \dim_x SS(M) = \dim_x V \) the module \( M \) is called holonomic.

3.1.2. Nuclear Fréchet spaces. For nuclear Fréchet spaces \( V \) and \( W \), \( V \otimes W \) will denote the completed projective tensor product and \( V^* \) will denote the continuous linear dual, endowed with the strong dual topology (see e.g. [Tre67, §50]).

Lemma 3.1.1 (Tre67 (50.18) and (50.19)). \((V \otimes W)^* \cong V^* \otimes W^* \) and \( L(V, W) \cong V^* \otimes W \).

3.1.3. Schwartz functions and tempered distributions. We will use the theory of Schwartz functions and tempered distributions on Nash manifolds, see e.g., [dCl91, AG08]. Nash manifolds are smooth semi-algebraic manifolds, e.g. real points of algebraic manifolds defined over \( \mathbb{R} \). This is the only type of Nash manifolds that appears in the current paper.

We denote the space of complex valued Schwartz functions on a Nash manifold \( Y \) by \( S(Y) \).

For a Nash bundle \( E \) on \( Y \), we denote its space of complexified Schwartz sections by \( S(E) \).

We denote by \( S^*(Y) \) the (continuous) dual space to \( S(Y) \), and call its elements tempered distributions. Similarly, we denote \( S^*(Y, E) := (S(Y, E))^* \) if \( E \) is a vector bundle over an algebraic manifold \( Y \) defined over \( \mathbb{R} \), we will also consider it as a Nash bundle over the Nash manifold \( Y \) of real points of \( Y \). For a Nash manifold \( Y \) we denote by \( S_Y^* \) the sheaf of tempered distributions on \( Y \) defined by \( S_Y^*(U) := S_Y^*(U) \).

For an algebraic manifold \( Y \) defined over \( \mathbb{R} \), we will denote by \( S_Y^* \) the quasi-coherent sheaf defined by \( S_Y^*(U) := S_Y^*(U) \).

The notion is local and is invariant with respect to linear transformations, it naturally extends to elements of \( S^*(Y, E) \).

Theorem 3.1.2 (Bernstein–Kashiwara, see e.g. [AGM16 Theorem 3.13], cf. [Kas83 Theorems 5.1.7 and 5.1.12]). Let \( Y \) be an algebraic manifold defined over \( \mathbb{R} \), and let \( M \) be a holonomic \( D_Y \)-module. Then the space of solutions \( \text{Hom}_{D_Y}(M, S_Y^*) \) is finite-dimensional.

We will also need the following version of the Schwartz Kernel theorem.

Lemma 3.1.3 (See e.g. [AG10 Corollary 2.6.3]). Let \( X \) and \( Y \) be Nash manifolds, and let \( E_1 \) and \( E_2 \) be Nash bundles on them. Then \( S(X \times Y, E_1 \boxtimes E_2) \cong S(X, E_1) \otimes S(Y, E_2) \).

3.1.4. Notation. Let \( X \) be the manifold of real points of an algebraic \( G \)-manifold \( X \). We will say that a \( G \)-equivariant bundle \( E \) on \( X \) is a twisted algebraic \( G \)-bundle if there exists a finite-dimensional (smooth) representation \( \sigma \) of \( G \) and an algebraic \( G \)-bundle \( E' \) on \( X \) such that \( E = E' \otimes \sigma \).

For any two-sided ideal \( I \subset U(g) \), denote by \( \mathcal{V}(I) \) its associated variety, i.e. the closed conical subset of \( g^* \) defined to be the set of zeros of the symbols (in \( S(g) \)) of the elements of \( I \). If \( I \) intersects the center \( z \) of \( U(g) \) by an ideal of finite codimension then \( \mathcal{V}(I) \) is known to be a union of nilpotent orbits.

Theorem 3.2.1. Let \( I \subset U(g) \) be a two-sided ideal, and let \( \mathcal{V}(I) \subset g^* \) denote its associated variety. Suppose that \( \mathcal{V}(I) \) is a union of finitely many \( G \)-orbits. Let \( X, Y \) be \( \mathcal{V}(I) \)-spherical \( G \)-manifolds. Let \( E_1, E_2 \) be twisted algebraic \( G \)-bundles on \( X \) and \( Y \) respectively.
Let $S^*(X \times Y, \mathcal{E}_1 \boxtimes \mathcal{E}_2)^{\Delta \mathfrak{g}, I}$ denote the subspace of $S^*(X \times Y, \mathcal{E}_1 \boxtimes \mathcal{E}_2)$ consisting of elements invariant under the diagonal action of $\mathfrak{g}$, and annihilated by the action of $I$ on the first coordinate. Then $S^*(X \times Y, \mathcal{E}_1 \boxtimes \mathcal{E}_2)^{\Delta \mathfrak{g}, I}$ is finite-dimensional, and consists of holonomic distributions.

For the proof we will need the following straightforward statements.

**Lemma 3.2.2.** Let $X$ be an algebraic manifold. Let $\mathcal{E}$ be a vector bundle over $X$, and let $\mathcal{O}_{X, \mathcal{E}}$ be the locally free coherent sheaf of regular sections of $\mathcal{E}$. Then we have canonical isomorphisms

$$\text{Hom}_{\mathcal{D}_X}(\mathcal{O}_{X, \mathcal{E}} \otimes_{\mathcal{O}_X} \mathcal{D}_X, S_X^*) \cong \text{Hom}_{\mathcal{O}_X}(\mathcal{O}_{X, \mathcal{E}}, S_X^*) \cong S^*(X, \mathcal{E})$$

such that

(i) these isomorphisms are functorial on the groupoid of pairs $(X, \mathcal{E})$

(ii) If a map $\varphi \in \text{Hom}_{\mathcal{D}_X}(\mathcal{O}_{X, \mathcal{E}} \otimes_{\mathcal{O}_X} \mathcal{D}_X, S_X^*)$ factors through a holonomic $\mathcal{D}_X$-module then the corresponding distribution in $S^*(X, \mathcal{E})$ is holonomic.

**Corollary 3.2.3.** Let an algebraic group $G$ act on an algebraic manifold $X$. Let $\mathcal{E}$ be a twisted algebraic $G$-bundle on $X$. Then we have an isomorphism of $\mathfrak{g}$-modules

$$\text{Hom}_{\mathcal{D}_X}(\mathcal{O}_{X, \mathcal{E}} \otimes_{\mathcal{O}_X} \mathcal{D}_X, S_X^*) \cong S^*(X, \mathcal{E})$$

**Proof of Theorem 3.2.1.** Consider $N := \mathcal{O}_{X \times Y, \mathcal{E}_1 \boxtimes \mathcal{E}_2} \otimes_{\mathcal{O}_{X \times Y}} \mathcal{D}_{X \times Y}$ as a $\mathcal{D}_{X \times Y}$-module equipped with an action of $\mathfrak{g} \times \mathfrak{g}$, and thus an action of $\mathcal{U}(\mathfrak{g}) \otimes C \mathcal{U}(\mathfrak{g})$. Let $J \subset \mathcal{U}(\mathfrak{g}) \otimes C \mathcal{U}(\mathfrak{g})$ be the ideal generated by $\Delta \mathfrak{g}$ and by $I \otimes 1$. Let $M := N/JN$. The right action of $\mathcal{D}_{X \times Y}$ on itself defines $\mathcal{D}_{X \times Y}$-module structures on $N$ and on $M$.

By Corollary 3.2.3 the linear space $S^*(X \times Y, \mathcal{E}_1 \boxtimes \mathcal{E}_2)^{\Delta \mathfrak{g}, I}$ is isomorphic to the space of solutions $\text{Hom}_{\mathcal{D}_{X \times Y}}(M, S_{X \times Y}^*)$. The singular support of $M$ lies in the preimage of

$$R = (\mathcal{V}(I) \times \mathcal{V}(I)) \cap (\Delta \mathfrak{g})^{-1}$$

under the moment map $\mu_{X \times Y} : T^*X \times T^*Y \to \mathfrak{g}^* \times \mathfrak{g}^*$. For every point $(x, -x) \in R$ with orbit $O \times O$ we have

$$\dim \mu^{-1}(\{(x, -x)\}) = \dim \mu_X^{-1}(O) + \dim \mu_Y^{-1}(O) - 2 \dim O \leq \dim X + \dim Y - \dim O.$$

Thus, $\dim \mu^{-1}(O \times O) \cap \Delta \mathfrak{g}^{-1} \leq \dim X \times Y$. Since $R$ is a finite union of sets of the form $(O \times O) \cap \Delta \mathfrak{g}^{-1}$, we get that $\dim \mu^{-1}(R) \leq \dim X \times Y$, and thus $M$ is holonomic. By Theorem 3.1.2 this implies that the space of solutions is finite-dimensional. By Lemma 3.2.2 the space $S^*(X \times Y, \mathcal{E}_1 \boxtimes \mathcal{E}_2)^{\Delta \mathfrak{g}, I}$ consists of holonomic distributions. 

4. Representation theory

Throughout the section we fix a connected linear algebraic group $G$ defined over $\mathbb{R}$.

4.1. Preliminaries. We denote by $\text{Rep}^\infty(G)$ the category of smooth nuclear Fréchet representations of $G$ of moderate growth. This is essentially the same definition as in [dC91] §1.4] with the additional assumption that the representation spaces are nuclear (see §3.1.2). For example, for any algebraic $G$-manifold $X$ and any twisted algebraic $G$-bundle $\mathcal{E}$ over $X$, the representation $S(X, \mathcal{E})$ lies in $\text{Rep}^\infty(G)$.

For any two-sided ideal $I \subset \mathcal{U}(\mathfrak{g})$, and any representation $\Pi \in \text{Rep}^\infty$, denote by $\Pi_I \in \text{Rep}^\infty$ the representation $\Pi/\Pi_I$, where $\Pi_I$ denotes the closure of the action of $I$.

For any Fréchet space $V$, [dC91] §1.2] defines the space of $V$-valued Schwartz functions $S(Y, V)$, and shows that the natural map $S(Y) \otimes V \rightarrow S(Y, V)$ is an isomorphism.
Definition 4.1.1. For a closed algebraic subgroup $H \subset G$ and $\pi \in \text{Rep}^\infty(H)$, we denote by $\text{ind}_H^G(\pi)$ the Schwartz induction as in [dCl91] §2. More precisely, in [dCl91] du Cloux considers the space $\mathcal{S}(G, \pi)$ of Schwartz functions from $G$ to the underlying space of $\pi$, and defines a map from $\mathcal{S}(G, \pi)$ to the space $C^\infty(G, \pi)$ of all smooth $\pi$-valued functions on $G$ by $f \mapsto \tilde{f}$, where

$$
\tilde{f}(x) = \int_{h \in H} \pi(h)f(h)dh,
$$

and $dh$ denotes a fixed left-invariant measure on $H$. The Schwartz induction $\text{ind}_H^G(\pi)$ is defined to be the image of this map. Note that $\text{ind}_H^G(\pi) \in \text{Rep}^\infty(G)$.

Definition 4.1.2. For $\pi \in \text{Rep}^\infty(G)$, denote by $\pi_G$ the space of coinvariants, i.e. quotient of $\pi$ by the intersection of kernels of all $G$-invariant functionals. Explicitly,

$$
\pi_G = \pi/\{\pi(g)v - v \mid v \in \pi, g \in G\}.
$$

Note that if $G$ is connected then $\pi_G = \pi/\overline{\mathfrak{g}\pi}$ which in turn is equal to the quotient of $H_0(\mathfrak{g}, \pi)$ by the closure of zero.

We will need the following two versions of the Frobenius reciprocity for Schwartz induction.

Lemma 4.1.3 ([GGS17, Lemma 2.3.4]). Let $\rho \in \text{Rep}^\infty(H)$, $\pi \in \text{Rep}^\infty(G)$ and let $\pi^*$ denote the dual representation, endowed with the strong dual topology. Then

$$
\text{Hom}_G(\text{ind}_H^G(\tau), \pi^*) \cong \text{Hom}_H(\tau, \pi^*\delta_H^{-1}\delta_G),
$$

where $\delta_H$ and $\delta_G$ denote the modular functions of $H$ and $G$.

Lemma 4.1.4 ([GGS21, Lemma 2.8]). Let $\tau \in \text{Rep}^\infty(H)$, $\pi \in \text{Rep}^\infty(G)$. Consider the diagonal actions of $H$ on $\pi \otimes \tau$ and of $G$ on $\pi \otimes \text{ind}_H^G(\tau)$. Then $(\pi \otimes \tau\delta_H\delta_G^{-1})_H \cong (\pi \otimes \text{ind}_H^G(\tau))_G$.

4.1.1. Admissible representations. Let us now define the category of representations to which our main results apply. We will call such representations admissible and denote the category of such representations by $\mathcal{M}(G)$. If $G$ is reductive then we let $\mathcal{M}(G) \subset \text{Rep}^\infty(G)$ be the subcategory of finitely generated admissible representations (see [Wall92, §11.5]).

For a general $G$, fix a Levi decomposition $G = M \ltimes U$.

Definition 4.1.5. We call a representation $\pi \in \text{Rep}^\infty(G)$ admissible if $\pi|_M$ is admissible and $\pi$ is $\mathcal{U}(u)$-finite, i.e. $\text{Ann}_{\mathcal{U}(u)} \pi$ has finite codimension in $\mathcal{U}(u)$.

Remark 4.1.6. This definition does not depend on the Levi decomposition.

The following proposition explains the structure of admissible representations of $G$.

Proposition 4.1.7. Any admissible $\pi \in \mathcal{M}(G)$ admits a finite filtration with associated graded pieces of the form $\pi_i \otimes \chi_i$ where $\pi_i \in \mathcal{M}(M)$ (considered as a representation of $G$ using the projection $G \to M$) and $\chi_i$ are unitary characters of $G$.

Proof. Since $\pi|_M$ is admissible, it has finite length. Thus $\pi$ also has finite length, and thus it is enough to show that $U$ acts by a unitary character on every irreducible $\pi \in \mathcal{M}(G)$.

Since $\text{Ann}_{\mathcal{U}(u)} \pi$ has finite codimension in $\mathcal{U}(u)$, the action of $u$ on $\pi$ is locally finite. Lie’s theorem implies now that $u$ acts by a character on a non-zero subspace of $\pi$, and thus so does $U$. Denote this character by $\psi$. We would like to show that $\psi$ is $G$-invariant. Since $\mathcal{U}(u)/\text{Ann}_{\mathcal{U}(u)} \pi$ is finite-dimensional, it has only finitely many simple modules. Therefore, there are only finitely
many $\psi_i$ with non-zero $(u, \psi_i)$-eigenspaces in $\pi$. We conclude that the $G$-orbit of $\psi$ is finite, and thus $\psi$ is fixed by $g$. Since $G$ is connected, and the action of $G$ on the space of characters of $u$ is algebraic, we get that $\psi$ is $G$-invariant. Hence so is the $\psi$-eigenspace of $u$ in $\pi$. It is easy to see that this space is closed, and thus it has to equal $\pi$. We can extend $\psi$ to $G$ and get $\pi = (\pi \otimes \psi^{-1}) \otimes \psi$. Finally, it is easy to see that all moderate growth characters of unipotent groups are unitary.

The requirement that $\pi$ is $U(u)$-finite implies that $V(\pi) \subset u^\perp \cong m^*$. This, together with the admissibility of $\pi|_M$, implies that $V(\pi)$ is a finite union of $G$-orbits. Vice versa, the inclusion $V(\pi) \subset u^\perp$ is also necessary to have finitely many orbits, by Proposition 2.1.2.

For any $\pi \in \mathcal{M}(G)$, we define the contragredient representation by $\tilde{\pi} := S(G)\pi^*$.

**Lemma 4.1.8.** $\tilde{\pi}|_M \cong (\pi|_M)$

*Proof.* We need to show that any $M$-smooth vector $v \in \pi^*$ is also $G$-smooth.

Step 1: Proof for the case when $\pi$ is irreducible.

By Proposition 4.1.7 we can write $\pi = \pi_1 \otimes \psi$, where $\pi_1 \in \mathcal{M}(M)$ and $\psi$ is a character. Then $v$ is infinitely differentiable under the action of $G$ on the Fréchet space $\pi|_M$. The Dixmier-Malliavin theorem implies now that $v$ is smooth, i.e. $v \in \tilde{\pi} = S(G)\pi^*$.

Step 2: Proof for the general case.

We prove by induction on the length of $\pi$. Let $\sigma \subset \pi$ be a closed irreducible submodule and let $v_0 := v|_\sigma$. By the previous step we can write $v_0 = \sum_i g_i \ast w_i$ where $g_i \in S(G)$, $w_i \in \sigma^*$ and the sum is finite. By the Hahn-Banach theorem there exist $w'_i \in \pi^*$ s.t. $w'_i|_\sigma = w_i$. Let $w := v - \sum_i g_i \ast w'_i$. It remains to show that $w$ is $G$-smooth. It is easy to see that $w|_\sigma = 0$. Hence the assertion follows from the induction assumption applied to $\pi/\sigma$.

□

The lemma implies that $\tilde{\pi} \cong \pi$. From this and Lemma 4.1.3 we obtain the following corollary.

**Corollary 4.1.9.** For any algebraic subgroup $H \subset G$ and any $\tau \in \mathcal{M}(H)$ and $\pi \in \mathcal{M}(G)$ we have

$$\text{Hom}_G(\text{ind}_H^G \tau, \pi) \cong \text{Hom}_{G \times H}(S(G), \pi \otimes \tau \delta^G_H),$$

where $G \times H$ acts on $G$ by left and right shifts.

*Proof.* Since $S(G) \otimes \text{ind}_H^G \tau = \text{ind}_H^G \tau$, we have $\text{Hom}_G(\text{ind}_H^G \tau, \pi) = \text{Hom}_G(\text{ind}_H^G \tau, \pi^*)$. By Lemma 4.1.3 we have

$$\text{Hom}_G(\text{ind}_H^G \tau, \pi) = \text{Hom}_G(\text{ind}_H^G \tau, \pi^*) \cong \text{Hom}_H(\tau, \pi^*|_H \delta^G_H \delta^G_H) \cong \text{Hom}_H(\tilde{\pi}|_H, \tau^* \delta^G_H \delta^G_H)$$

Now we note that $S(G) \cong \text{ind}_{\Delta^G_H} \mathbb{C}$ and use Lemma 4.1.3 again.

$$\text{Hom}(\tilde{\pi}|_H, \tau^* \delta^G_H \delta^G_H) \cong \text{Hom}_{\Delta^G_H}(\mathbb{C}, \tilde{\pi}^* \otimes \tau^* \delta^G_H \delta^G_H) \cong \text{Hom}_{G \times H}(S(G), \tilde{\pi}^* \otimes \tau^* \delta^G_H \delta^G_H)$$

$$\cong \text{Hom}_{G \times H}(S(G), \pi \otimes \tau \delta^G_H)$$

□

**Proposition 4.1.10 ([Cas89 Corollary 5.8]).** Let $K \subset M$ be a maximal compact subgroup, and let $V$ be an $(m, K)$-module. Suppose that its annihilator $\text{Ann}(V) \subset U(m)$ has finite codimension, and that $V$ has finite multiplicities as a representation of $K$. Then $V$ has finite length.
Definition 4.1.11. For any $\Pi, \tau \in \text{Rep}^\infty(G)$, we define the multiplicity of $\tau$ in $\Pi$ as
$$m(\Pi, \tau) := \dim \text{Hom}_G(\Pi, \tau).$$
We say that $\Pi$ has finite multiplicities if $m(\Pi, \tau)$ is finite for every $\tau \in \mathcal{M}(G)$.

For any $\mathfrak{g}$-module $\pi$, denote by $\text{Ann}(\pi) \subset \mathfrak{g}^*$ the associated variety of the annihilator of $M$ in $\mathcal{U}(\mathfrak{g})$, i.e. $\text{Ann}(\pi) = \mathcal{V}(\text{Ann}(\pi))$.

If $\pi \in \mathcal{M}(G)$, $\text{Ann}(\pi)$ is a union of nilpotent orbits in $\mathfrak{m}^*$. For any closed conical $G$-invariant subset $\Xi \subset \mathcal{N}(\mathfrak{m}^*) \subset \mathfrak{g}^*$, denote by $\mathcal{M}_\Xi(G) \subset \mathcal{M}(G)$ the subcategory consisting of representations $\pi$ with $\text{Ann}(\pi) \subset \Xi$.

4.2. Main results. Fix a Levi decomposition $G = MU$, and let $X$ be an algebraic $G$-manifold.

The natural projection $p : \mathfrak{g} \to \mathfrak{m}$ defines an embedding $i : \mathfrak{m}^* \hookrightarrow \mathfrak{g}^*$. Let $\mathfrak{z}(\mathfrak{m})$ denote the center of $\mathcal{U}(\mathfrak{m})$.

Theorem 4.2.1. Let $I \subset \mathcal{U}(\mathfrak{g})$ be a two-sided ideal such that $I \cap \mathfrak{z}(\mathfrak{m})$ is cofinite in $\mathfrak{z}(\mathfrak{m})$, and $I \cap \mathcal{U}(\mathfrak{u})$ is cofinite in $\mathcal{U}(\mathfrak{u})$. Assume that $X$ is $\mathcal{V}(I)$-spherical, and let $\mathcal{E}$ be a twisted algebraic $G$-equivariant vector bundle on $X$. Then $\mathcal{S}(X, \mathcal{E})_I \subset \mathcal{M}(G)$.

Proof. We have $\mathcal{S}(X, \mathcal{E}) \in \text{Rep}^\infty(G)$, and thus $\mathcal{S}(X, \mathcal{E})_I \subset \text{Rep}^\infty(G)$. Thus, by the assumptions on $I$, it is enough to show that $\mathcal{S}(X, \mathcal{E})_I \subset \mathcal{M}(M)$.

Let $K \subset M$ denote the maximal compact subgroup, and let $K$ be the corresponding subgroup of $M$. Since $\mathcal{S}(X, \mathcal{E})_I$ is $\mathfrak{z}(\mathfrak{m})$-finite, by Proposition 4.1.10 it is enough to show that it has finite multiplicities as a representation of $K$. Let $\mathcal{E}'$ denote the tensor product of the dual bundle to $\mathcal{E}$ with the bundle of densities on $X$. Then $\mathcal{S}((X, \mathcal{E})_I)^* \cong \mathcal{S}(X, \mathcal{E}')_I$. Fix a $K$-type $\rho \in \hat{K}$.

We have $\text{Hom}_K(\mathcal{S}(X, \mathcal{E})_I, \rho^*) \cong \text{Hom}_K(\rho, \mathcal{S}(X, \mathcal{E}')_I)$, and by Lemma 4.1.3 we have
$$\text{Hom}_K(\rho, \mathcal{S}(X, \mathcal{E}')_I) \cong \text{Hom}_G(\delta_G \text{ind}^G_K \rho, \mathcal{S}(X, \mathcal{E}')_I)$$

Let $\mathcal{E}''$ be the twisted algebraic $G$-equivariant vector bundle on $G/K$ such that $\delta_G \text{ind}^G_K \rho \cong \mathcal{S}(G/K, \mathcal{E}'')$. By Lemmas 3.1.1 and 3.1.3
$$\text{Hom}_G(\delta_G \text{ind}^G_K \rho, \mathcal{S}(X, \mathcal{E}')_I) \cong \mathcal{S}(G/K \times X, \mathcal{E}'' \boxtimes \mathcal{E}')^{I, \Delta G}$$

Since $I \cap \mathcal{U}(\mathfrak{u})$ is cofinite in $\mathcal{U}(\mathfrak{u})$, we have $\mathcal{V}(I) \subset \mathfrak{m}^*$. Since $I \cap \mathfrak{z}(\mathfrak{m})$ is cofinite in $\mathfrak{z}(\mathfrak{m})$, we further have $\mathcal{V}(I) \subset \mathcal{N}(\mathfrak{m}^*)$. By Corollary 2.2.1, we obtain that $\mathcal{M}/K$ is a $\mathcal{V}(I)$-spherical $\mathcal{M}$-manifold, which by Lemma 2.2.2 implies that $\mathcal{G}/K$ is a $\mathcal{V}(I)$-spherical $\mathcal{G}$-manifold. By Theorem 3.2.1, the space $\mathcal{S}(G/K \times X, \mathcal{E}'' \boxtimes \mathcal{E}')^{I, \Delta G}^{I, \Delta G}$ is finite-dimensional. \hfill $\square$

It is easy to see that the condition that $I \cap \mathfrak{z}(\mathfrak{m})$ is cofinite in $\mathfrak{z}(\mathfrak{m})$ does not depend on the choice of the Levi decomposition.

Corollary 4.2.2. Let $\Xi \subset \mathcal{N}(\mathfrak{m}^*)$ be a closed conical subset. Assume that $X$ is $\Xi$-spherical, and let $\mathcal{E}$ be a twisted algebraic $G$-equivariant vector bundle on $X$. Then any $\pi \in \mathcal{M}_\Xi(G)$ has (at most) finite multiplicity in $\mathcal{S}(X, \mathcal{E} \otimes \sigma)$, i.e. $\dim \text{Hom}_G(\mathcal{S}(X, \mathcal{E}), \pi) < \infty$.

The corollary follows from Theorem 4.2.1 by taking $I := \text{Ann}(\pi)$.

Remark 4.2.3. Corollary 4.2.2 stays true under a weaker assumption on $\pi$: it works for any $\mathfrak{g}$-module $\pi$, such that $\mathcal{V}(\pi) \subset \Xi$, and the action of $\mathfrak{m}$ on $\pi$ integrates to an admissible representation of $M$. Indeed, the argument in the proof of Theorem 4.2.1 shows that the assumption $\mathcal{V}(\pi) \subset \Xi$ implies that $\mathcal{S}(X, \mathcal{E})_{\text{Ann} \pi} \subset \mathcal{M}(M)$.
Corollary 4.2.4. If $G$ is reductive and $X$ is spherical then for every ideal $J \subset \mathcal{U}(\mathfrak{g})$ of finite codimension, $S(X,\mathcal{E})_{\mathcal{U}(\mathfrak{g})} \in \mathcal{M}(G)$.

Corollary 4.2.5. Assume that $G$ is reductive and let $\Pi \in \text{Rep}^\infty(G)$. Then the following are equivalent

(i) $\Pi$ has finite multiplicities
(ii) For any ideal $J \subset \mathcal{U}(\mathfrak{g})$ of finite codimension, $\Pi_{\mathcal{U}(\mathfrak{g})} \in \mathcal{M}(G)$.

Proof. (ii) $\Rightarrow$ (i) is obvious. For the implication (i) $\Rightarrow$ (ii) denote $I := \mathcal{U}(\mathfrak{g})$. By Proposition 4.1.10 it is enough to show that any $K$-type has finite multiplicities. To show this it is again enough to show that every $K$-type has finite multiplicities in it. Using the compactness of $K$ and Lemma 4.1.4 we have

$$\sigma \otimes_K \Pi_I \cong \text{ind}_K^G \sigma \otimes_G \Pi_I \cong (\text{ind}_K^G \sigma)_I \otimes_G \Pi,$$

and to show that this is finite-dimensional it is enough to show that $(\text{ind}_K^G \sigma)_I$ has finite length (since $\Pi$ has finite multiplicities). To show this it is again enough to show that every $K$-type has finite multiplicities in it. Using the compactness of $K$ and Lemma 4.1.4 we have

$$\text{Hom}_K(\rho, (\text{ind}_K^G \sigma)_I) \cong (\rho^* \otimes (\text{ind}_K^G \sigma)_I)_K \cong (\text{ind}_K^G \rho^* \otimes (\text{ind}_K^G \sigma)_I)_G$$

Since $I$ is central, $I \times I$ acts on $(\text{ind}_K^G \rho^* \otimes \text{ind}_K^G \sigma)_G$, and we have

$$(\text{ind}_K^G \rho^* \otimes (\text{ind}_K^G \sigma)_I)_G \cong ((\text{ind}_K^G \rho^* \otimes \text{ind}_K^G \sigma)_G)_{I \times I}$$

Since $K$ is compact, we have

$$(\text{ind}_K^G \rho^* \otimes \text{ind}_K^G \sigma)_G \cong \text{Hom}_{K \times K}(\rho \otimes \sigma^*, S(G \times G/\Delta G))$$

Altogether, we have $\text{Hom}_K(\rho, (\text{ind}_K^G \sigma)_I) \cong \text{Hom}_{K \times K}(\rho \otimes \sigma^*, S(G \times G/\Delta G)_{I \times I})$, which is finite-dimensional since $S(G \times G/\Delta G)_{I \times I} \in \mathcal{M}(G \times G)$ by Corollary 4.2.4.

4.3. Applications to branching problems. Let $H \subset G$ be an algebraic subgroup defined over $\mathbb{R}$. Let $L$ denote the quotient of $H$ by its unipotent radical, and let $p_L : H \to L$ denote the projection.

Proposition 4.3.1. Let $O_1 \subset \mathfrak{m}^*$ and $O_2 \subset \mathfrak{t}^*$ be nilpotent orbits. Suppose that one of the following holds:

(a) $G \times H/\Delta H$ is $\overline{O}_1 \times \overline{O}_2$-spherical
(b) $\dim O_1^1 \cap p_0^{-1}(O_2^2) \leq (\dim O_1^1 + \dim O_2^2)/2$ for any $O_1^1 \subset \overline{O}_1$ and $O_2^2 \subset \overline{O}_2$.
(c) $O_1 = O_P$ for some parabolic subgroup $P \subset \mathbb{M}$ and $\mathbb{M}/P$ is an $\overline{O}_2$-spherical $H$-space.
(d) $O_2 = O_Q$ for some parabolic subgroup $Q \subset L$ and $G/P_L^{-1}(Q)$ is an $\overline{O}_1$-spherical $G$-space.

Then for every $\pi \in \mathcal{M}_{\overline{O}_1}(G)$ and $\tau \in \mathcal{M}_{\overline{O}_2}(H)$, we have

$$\dim \text{Hom}_H(\pi|_H, \tau) < \infty$$

Proof. By Lemma 2.2.5 and Proposition 2.3.1 any of the conditions (i) - (ii) implies (a). We will thus assume that (a) holds. By Corollary 4.2.2 this implies that for every $\pi \in \mathcal{M}_{\overline{O}_1}(G)$ and $\tau \in \mathcal{M}_{\overline{O}_2}(H)$,

$$\dim \text{Hom}_{G \times H}(S(G \times H/\Delta H), \pi \otimes \delta_G \otimes \tau) < \infty.$$
Now we note that $S(G \times H/\Delta H) = \text{ind}_{\Delta H}^{G \times H}$ and by Frobenius reciprocity for Schwartz induction (Lemma 4.1.3) we have:

$$\text{Hom}_{G \times H}(S(G \times H/\Delta H), \pi \otimes \delta_G \otimes \tau) \cong \text{Hom}_{G \times H}(\text{ind}_{\Delta H}^{G \times H} \mathbb{C}, (\pi \otimes \delta_G)^* \otimes \tau) \cong (\pi^* \otimes \tau)^{\Delta H} \cong \text{Hom}_H(\pi|_H, \tau)$$

Corollary 4.3.2. Let $\Xi \subset N(m^*)$ be a closed $G$-invariant subset, and suppose that $G/H$ is $\Xi$-spherical. Then for any $\pi \in \mathcal{M}_\Xi(G)$ and any finite-dimensional $\tau \in \mathcal{M}(H)$ we have

$$\dim \text{Hom}_H(\pi|_H, \tau) < \infty$$

Corollary 4.3.3. Suppose that $G$ is reductive, and that the unipotent radical $V$ of $H$ equals the unipotent radical of a parabolic subgroup $R \subset G$. Let $Q \subset L$ be a parabolic subgroup, and suppose that $Q$ is a spherical subgroup of $R/V$. Then for every $\tau \in \mathcal{M}_{O_Q}(H)$, the induction $\text{ind}_R^L \tau$ has finite multiplicities.

Proof. By the assumption $Q$ is a spherical subgroup of $R/V$. This implies that the parabolically induced subgroup $QV \subset G$ is also spherical. By Corollary 2.2.1 this implies that the condition $(d)$ of Proposition 4.3.1 is satisfied for any nilpotent orbit $O_1 \subset g^*$. Thus for every $\pi \in \mathcal{M}(G)$ we have $\dim \text{Hom}_H(\pi|_H, \tau) < \infty$. The corollary follows now from Corollary 4.1.9 on Frobenius reciprocity.

Proof of Corollary 4.3.3 In this corollary both $G$ and $H$ are reductive. Thus part $(\mathbb{I})$ follows from the previous corollary by taking $R = G$. To prove part $(\mathbb{II})$ we first apply Corollary 2.2.1 which says that since $G/P$ is a spherical $H$-variety, it is $\overline{O_2}$-spherical for every nilpotent orbit $O_2 \subset h^*$. Thus, the condition $(c)$ of Proposition 4.3.1 is satisfied and the finiteness of multiplicities follows.

Proof of Example 2.2.1 Let $G$ be $GL_{2n}$, $L' \subset G$ be the Levi subgroup $GL_n \times GL_n$, $R = L'/V$ be the corresponding standard parabolic, $L := \Delta GL_n \subset L'$, and $H = LV$. Let $Q \subset L$ be the mirabolic subgroup. Then it is easy to see that $Q$ is a spherical subgroup of $L$ (this is also shown in [MWZ99] and [Ste03]). By Corollary 4.3.3 this implies that for every $\tau \in \mathcal{M}_{O_Q}(H)$, the induction $\text{ind}_R^L \tau$ has finite multiplicities.

Appendix A. Proof of Proposition 2.1.2

Let $G$ be an algebraic group, $U$ be its unipotent radical, and $M = G/U$.

For the proof we will need the following lemma.

Lemma A.0.1. Let $V$ be an $m$-module, and let $v \in V$ be a non-zero vector such that there exists a semi-simple $s \in m$ with $sv = v$. Then there exists a non-nilpotent $t \in m^*$ that is orthogonal to the stabilizer $m_v$ of $v$.

Proof. Let $l := m^s \subset m$ denote the centralizer of $s$. We have a decomposition $m = l \oplus r$, where $r$ is the direct sum of all eigenspaces of $ad(s)$ on $m$ corresponding to non-zero eigenvalues. This defines a dual decomposition $m^* = l^* \oplus r^*$, with $l^*$ orthogonal to $r$. Under this decomposition, an element $t \in l^*$ is nilpotent as an element of $l^*$ if and only if it is nilpotent as an element...
of $m^*$. One can see this using an identification $m \cong m^*$ given by a non-degenerate invariant quadratic form.

Since the adjoint action of $s$ preserves $m$, we have a decomposition $m = l \oplus r$. Thus it is enough to find a non-nilpotent element $t \in l^*$ orthogonal to $l$.

Let $e$ denote the center of $l$. We will prove more: there exists $t \in l^*$ that does not lie in $e^\perp$. Suppose the contrary: $l^* \subset e^\perp$. But then $e \subset l$, which is not true since $s \in e$ and $s \not\in l$. \qed

**Proof of Proposition 2.1.2.** We will prove the proposition by induction on the depth of $u$. Let $e$ be the center of $u$. By the induction hypothesis, it is enough to prove that $\Xi \subset e^\perp$. Assume the contrary, and let $O \subset \Xi$ be an open orbit s.t. $O \not\subset e^\perp$. Let $p : g^* \to e^*$ denote the restriction. We will consider the Lie algebra action of $g$ on $g^*$. For $\alpha \in g$ and $v \in g^*$ we will denote the result of this action by $\alpha \cdot v$. Since $U$ acts trivially on $e$ and on $e^*$, the action of $G$ on $e^*$ factors through $M$.

**Step 1.** For any $y \in p(O)$ there exists $\mu_y \in m$ s.t. $\mu_y \cdot y = y$.

Let $x \in p^{-1}(y) \cap O$, and let $\Lambda := \text{Span}\{x\}$. Since $\Xi$ is conical and $O$ is open in $\Xi$, $l \cap O$ is open in $l$. Thus $x$ lies in the tangent space to $O$ at $x$. Thus there exists some $\alpha \in g$ s.t. $\alpha \cdot x = x$. Since $p$ is $G$-equivariant, we have $\alpha \cdot y = y$, and thus $\mu_y \cdot y = y$, where $\mu_y$ is the projection of $\alpha$ to $m \cong g/u$.

**Step 2.** For any $y \in p(O)$ there is a semi-simple $s_y \in m$ s.t. $s_y \cdot y = y$. By semi-simple we mean that $s_y$ acts semi-simply on any algebraic representation of $M$.

Let $\mu_y$ be as in the previous step, and let $\mu_y = s_y + n_y$ be the Jordan decomposition of $\mu_y$. Since $n_y$ acts nilpotently on $e^*$, and the actions of $s_y$ and $n_y$ commute, we have $s_y \cdot y = y$.

**Step 3.** For any $y \in p(O)$, there exists a non-nilpotent $t_y \in m^*$ such that $O \cap p^{-1}(y)$ is locally invariant w.r.t. shifts in $t_y$, i.e. for any $x \in O \cap p^{-1}(y)$, we have $t_y \in T_x(O \cap p^{-1}(y))$.

Fix $y \in p(O)$. By the previous step and Lemma 2.1.1, there exists a non-nilpotent $t_y \in m^*$ orthogonal to the stabilizer of $y$ in $m$. Let $x \in O \cap p^{-1}(y)$. It is enough to show that $e \cdot x \not\subset t_y$. Consider the map $\phi_x : e \to g^*$ defined by $\phi(\alpha) := \alpha \cdot x$. It is easy to see that $\text{Im}(\phi) \subset m^*$. Thus we will consider $\phi$ as a map $e \to m^*$. Let $\psi = \phi^* : m \to e^*$. Then $\text{Im}(\psi) = (\text{Ker}\psi)^\perp$. It is easy to see that $\psi(\alpha) = \alpha \cdot y$. Thus $\text{Ker}\psi = m_y$. Thus, $t_y \in (\text{Ker}\psi)^\perp = \text{Im}(\phi) = e \cdot x$.

**Step 4.** For any $y \in p(O)$, there exists non-nilpotent $t_y \in m^*$ such that $\overline{O} \cap p^{-1}(y)$ includes an affine line in the direction of $t_y$ through any point $x \in O \cap p^{-1}(y)$.

We take $t_y$ as in the previous case. Note that $O \cap p^{-1}(y)$ is an orbit of $G_y$ and thus is smooth. Let $N := (\overline{O} \cap p^{-1}(y))(\mathbb{C})$. We can consider $t_y$ as a constant vector filed on $N$. Let $x \in N$. The existence and uniqueness theorem for solutions of ODEs imply that $x + C_{t_y} \cap N$ is open in $x + C_{t_y}$ and thus it is Zariski dense in $x + C_{t_y}$. Let $L \subset p^{-1}(y)$ be the affine line through $x$ in direction $t_y$. We get that $L \cap \overline{O} \cap p^{-1}(y)$ is Zariski dense in $L$. But it is also closed there. Therefore $L \cap \overline{O} \cap p^{-1}(y) = L$.

**Step 5.** There exists non-nilpotent $t_0 \in \overline{O} \cap m^*$.

Take $y \in p(O)$ and $x \in O \cap p^{-1}(y)$. Let $\Lambda := \text{Span}\{x\}$ and $\Pi := \text{Span}\{x, t_y\}$. Since $\Xi$ is conical and $O$ is open in $\Xi$, $\Lambda \cap O$ is dense in $\Lambda$. Together with the previous step, this implies that $\Pi \cap O$ is dense in $\Pi$. Therefore $\Pi \subset \overline{O}$, and thus $t_y \in \overline{O} \cap m^*$.

**Step 6.** Contradiction.
The fact that $O \cap m^*$ is conical and has finitely many orbits implies that it lies inside the nilpotent cone of $m^*$. This contradicts the previous step.

□

Appendix B. Example of strict inequality in Definition A - by Ido Karshon

Let $W$ be a symplectic vector space of dimension $2n$. Let $G := \text{Sp}(W) \times \text{Sp}(W \oplus W)$ and $H := \{(Y, \begin{pmatrix} Y & 0 \\ 0 & Y \end{pmatrix}) \} \subset G$

Then $\mathfrak{h}^\perp := \{(-(A + C), \begin{pmatrix} A & B \\ -B^* & C \end{pmatrix})|A = -A^*, C = -C^* \} \subset \mathfrak{g}$, where $A^*, B^*$, and $C^*$ denote the conjugate operators w.r. to the symplectic form. Let $O \subset \mathcal{N}(\mathfrak{g}^*)$ be the product of minimal orbits of $\mathfrak{sp}^*(W)$ and $\mathfrak{sp}^*(W \oplus W)$. We identify $\mathfrak{g}$ with $\mathfrak{g}^*$ using the Killing form, and recall that the minimal orbit in the symplectic Lie algebra consists of rank one operators of the form $vv^*$, where $v$ is a vector. Thus $\mathfrak{h}^\perp \cap O = \{(-(aa^* + bb^*), \begin{pmatrix} aa^* & ab^* \\ ba^* & bb^* \end{pmatrix})|a, b \in W$ are colinear $\} \subset \mathfrak{g}$

Thus $\dim \mathfrak{h}^\perp \cap O = \dim W + 1$, while $\dim O = 3 \dim W$. Thus for $\dim W > 2$ we have $\dim \mathfrak{h}^\perp \cap O < \dim O/2$, and thus, by Corollary 2.2.4, $\dim \mu_{G/H}^{-1}(O) < \dim G/H + \dim O/2$.
